

# The Color Coding System

Four colors, one rule: the cloth that touches a toilet never touches a desk. Color coding makes cross contamination control something you can see across the room.

## Why Color Coding Exists

Germes do not stay where they started; they ride on cloths, mop heads, and gloves. One red cloth used in the wrong place can carry restroom bacteria to a break room table. Color coding stops that with a system so simple it works on the busiest night: every color has a territory, and colors never cross the line.

## Microfiber Cloths

| COLOR             | WHERE IT CLEANS                                             | NEVER TOUCHES                                      |
|-------------------|-------------------------------------------------------------|----------------------------------------------------|
| <b>Red / Pink</b> | Toilets, urinals, and the surfaces right around them        | Anything outside the restroom                      |
| <b>Yellow</b>     | Restroom sinks, counters, partitions, dispensers, and doors | Toilets and urinals; anything outside the restroom |
| <b>Blue</b>       | Glass, mirrors, and polished surfaces                       | Restroom fixtures                                  |
| <b>Green</b>      | Desks, tables, counters, dusting, and general surfaces      | Restrooms                                          |

## Mops Follow the Same Logic

| MOP COLOR            | TERRITORY                                                                                |
|----------------------|------------------------------------------------------------------------------------------|
| <b>Green or Blue</b> | Common areas: lobbies, hallways, break rooms, offices                                    |
| <b>Red / Pink</b>    | Restrooms only. Red pads and red buckets live in the restroom rotation and nowhere else. |

## Specialty Facilities Add Zones

Medical, clean room, and GMP food accounts extend the same idea with extra zone colors. The account's posted color map always wins; these are the common patterns:

| COLOR               | MEDICAL                         | GMP / FOOD                                          |
|---------------------|---------------------------------|-----------------------------------------------------|
| ● <b>Orange</b>     | Treatment rooms                 | Production & processing floor                       |
| ● <b>Yellow</b>     | Isolation rooms (dedicated kit) | Allergen control & segregated zones (dedicated kit) |
| ● <b>Light Blue</b> | Glass & viewing panels          | Glass & viewing panels                              |
| ● <b>Blue</b>       | Break rooms & offices           | Break rooms & offices                               |

## The Five Rules

- ☐ One color, one territory. No exceptions, no borrowing when you run short.
- ☐ Fold the cloth in quarters and rotate to a fresh face; 8 faces per cloth.
- ☐ Retire the cloth when the zone is done or every face is used, whichever comes first.
- ☐ Launder colors separately, and launder specialty zone colors (yellow zone kits) on their own.
- ☐ When in doubt, throw it in the dirty bag. A clean cloth costs cents; a lost account costs everything.
